Model Calibration and Validation

We calibrated the model to TB and HIV longitudinal data from South Africa [1,2]. A small subset of parameters that could not be estimated from the literature or prior studies were fit to the data: population growth, TB and HIV transmission, background and disease-specific mortality, and treatment coverage parameters (S1 Table). For these parameters only, values were independently randomly sampled from plausible ranges derived from the literature, then supplied to model simulations to generate putative outcomes for TB and HIV incidence and prevalence. Outcomes were evaluated by least sums of squared differences to assess the goodness of fit of the predicted TB and HIV incidence and prevalence relative to the longitudinal data. Standard score normalization was used to weight all data points equally: $z = \frac{x-\mu}{\sigma}$, where z is the normalized data point, x is the data point before normalization, μ is the mean of the data points, and σ is the standard deviation of the data points. To identify the best-fit parameter values, we randomly sampled fitted parameter values to generate 100,000 model outcomes, selecting the set of parameters that produced the lowest sum of squared differences. Ranges for fitted parameters (used in sensitivity and uncertainty analyses) were determined by restricting parameter values to only those combinations that produced model outcome estimates within the minimum and maximum of the TB incidence, prevalence, and case detection rate longitudinal data.

To validate our model, we compared our model outcome predictions to the longitudinal data to which parameters were fit (S1 Fig. and S2 Table). We additionally compared our model predictions to observed data that were not used in the model calibration: prevalence of MDR and XDR-TB and estimated ART coverage (S2 Table).

Uncertainty and Sensitivity Analyses

To account for uncertainty in parameter estimates, we specified probability distributions encompassing values ranging from the minimum to maximum estimate for each parameter (S1 Table), and then evaluated the model outcomes predicted from random samples of those distributions. We specified Beta distributions for all parameters whose ranges were constrained between zero and one (*i.e.*, probabilities and proportions). Gamma distributions were specified for rate parameters. The means of the Beta and Gamma distributions were set to the best-fit parameter estimates. The variances were calculated based on the uniform distributions between the minimum and maximum estimates from the literature ($\text{variance} = \frac{1}{12}(\text{maximum} - \text{minimum})^2$; S1 Table), and distributions were truncated by the minimum and maximum estimates. To efficiently draw a collection of variates from the probability distributions, Latin hypercube sampling was applied. These variates were used to parameterize the model and generate outcomes. The central 95% of each outcome was identified as representing our uncertainty. This uncertainty was demarcated by the error bars in the figures of the main results. Partial rank correlation coefficients (PRCCs) were calculated for model outcomes when CICF was implemented at an annual screening rate. PRCCs are listed in S3 Table.

Model Equations

Our model consists of differential equations, characterizing joint TB and HIV transmission in a rural community in South Africa. The modeled disease states are listed in S4 Table. For clarity, here we describe TB and HIV transmission separately, where X corresponds to the TB disease state; Y corresponds to the HIV disease state; $i = \text{infectious or noninfectious TB}$; and $j = \text{DS } (j=1)$, MDR $(j=2)$, or XDR $(j=3)$ TB; $^T = \text{TB}$; $^H = \text{HIV}$.

Drug Susceptible TB

S2 Fig. CICF with ART eligibility at CD4+ cell count \leq 500 cells per milliliter. Impact of increasing eligibility to initiate ART from CD4+ cell count \leq 350 cells per milliliter to a CD4+ cell count \leq 500 cells per milliliter, and assuming ART coverage for individuals with a CD4+ cell count between 350 and 500 cells per milliliter is equal to the ART coverage for individuals with a CD4+ cell count below 350 cells per milliliter, on total TB cases averted, HIV infections averted, drug susceptible TB (DS TB) cases averted, MDR-TB cases averted, XDR-TB cases averted, and TB/HIV deaths averted by CICF at frequencies corresponding to screening individuals on average once every five years (annual frequency = 0.20), once every four years (annual frequency = 0.25), once every three years (annual frequency = 0.33), once every two years (annual frequency = 0.5), annually (annual frequency = 1), two times annually (annual frequency = 2), three times annually (annual frequency = 3), four times annually (annual frequency = 4), and five times annually (annual frequency = 5).

S3 Fig. Decreased ART Efficacy. Impact of decreasing ART efficacy on total TB cases averted, HIV infections averted, drug susceptible TB (DS TB) cases averted, MDR-TB cases averted, XDR-TB cases averted, and TB/HIV deaths averted by expanding ART coverage to 80% and increasing five-year retention to 70% by 2016. Note that Total TB and DS TB lines overlap because they are very close in value; the majority of total TB cases are drug susceptible.

S4 Fig. Expansion of ART coverage with ART eligibility at CD4+ cell count ≤ 500 cells per milliliter. Impact of increasing eligibility to initiate ART from CD4+ cell count ≤ 350 cells per milliliter to a CD4+ cell count ≤ 500 cells per milliliter, with ART coverage for individuals with a CD4+ cell count between 350 and 500 cells per milliliter varied between 0% and 100% of the ART coverage for individuals with a CD4+ cell count ≤ 350 cells per milliliter, on total TB cases averted, HIV infections averted, drug susceptible TB (DS TB) cases averted, MDR-TB cases averted, XDR-TB cases averted, and TB/HIV deaths averted by expanding ART coverage to 80% and increasing five-year retention to 70% by 2016. Note that Total TB and DS TB lines overlap because they are very close in value; the majority of total TB cases are drug susceptible.

S1 Table. Model parameters, ranges, and references. Rates are in units of year⁻¹ unless otherwise noted. *HIV+ individuals on ART have the effect of HIV on the natural history of TB reduced by the effectiveness of ART (parameter *treat*).

Parameter	Symbol	TB Disease Status	HIV-	HIV+ (No ART)	HIV+ (ART)	Reference
Annual population growth rate	g		0.0572 (0.02–0.06)	NA	NA	Fitted to [1,2]

S4 Table. Modeled Disease States.

Disease State	Description
TB	
<i>S</i>	Susceptible
<i>P_S</i>	Susceptible receiving IPT
<i>L</i>	Latent infection, slow
<i>E</i>	Latent infection, fast
<i>P_L</i>	Latent infection receiving IPT
<i>A</i>	Active infection
<i>T</i>	Active infection on effective TB treatment
<i>F</i>	Active infection in ineffective TB treatment
<i>D</i>	Active infection detected and awaiting culture/DST results
<i>R</i>	Recovered
<i>P_R</i>	Recovered receiving IPT
HIV	
<i>S</i>	Susceptible
<i>I</i>	Infected, CD4+ cell count > 350 cells/ml
<i>E</i>	Infected, CD4+ cell count \leq 350 cells/ml
<i>I_{ART}</i>	Infected and on ART at CD4+ cell count > 350 cells/ml
<i>E_{ART}</i>	Infected and on ART at CD4+ cell count \leq 350 cells/ml
